(54) Title: IMPLANTABLE MEDICAL DEVICE WITH VOICE RESPONDING AND RECORDING CAPACITY

WO 01/28627 A1

(57) Abstract: An implantable medical device such as a cardiac pacemaker or implantable cardioverter/defibrillator with the capability of receiving communications in the form of speech spoken by the patient. An acoustic transducer is incorporated within the device which along with associated filtering circuitry enables the voice communication to be used to affect the operation of the device or recorded for later playback.

IMPLANTABLE MEDICAL DEVICE WITH VOICE RESPONDING AND RECORDING CAPACITY

Cross-Reference to Related Applications

This application is a continuation-in-part of U.S. Patent Application No. 09/421,746, filed on October 20, 1999, which is incorporated herein by reference.

5

Field of the Invention

This invention pertains to implantable medical devices and to methods and systems for operating same. In particular, the invention relates to means for communicating with such devices.

Background

10 Modern pacemakers typically have the capability to communicate data via a radio-frequency link with an external programming device. Such data is transmitted to the pacemaker in order to program its mode of operation as well as define other operating parameters. Data transmitted from the pacemaker can be used to verify the operating parameters as well as relay information regarding the
15 condition of both the pacemaker and the patient. Pacemaker patients are monitored at regular intervals as part of routine patient care and to check the condition of the device. Among the data which may typically be telemetered from the pacemaker are its programming parameters and an electrogram representing the electrical activity of the heart as sensed by the pacemaker.

20 Pacemakers have also been developed which monitor certain parameters over time while the device is functioning in the patient. Data representing these parameters can be stored in memory for later retrieval using an external programmer.

Summary of the Invention

25 It would be desirable in certain situations to be able to communicate with an implantable medical device such as a pacemaker without the need for an external programming device or any kind of equipment such as a radio transmitter/receiver. This would enable a patient, for example, to alter the operation of the device by such communication at any time or place as the need

arises. Furthermore, the data recording capabilities of the implantable medical device could be activated by the patient whenever subjective symptoms are noted. The recorded data could then be retrieved later and analyzed for correlation with the symptoms experienced by the patient.

5 Accordingly, in one embodiment, the present invention is an implantable medical device, such as a cardiac pacemaker or implantable cardioverter/defibrillator, having incorporated therein a system enabling voice communication with the device so that the device responds to voice commands. The system includes an acoustic transducer and processing circuitry for sensing a 10 patient's voice and deriving messages from words spoken by the patient, which messages may then alter the operation of the device. When a patient in whom the device is implanted speaks, the vibrating chords of the larynx cause acoustical energy to be radiated into the thorax where the acoustic transducer converts the energy into electrical audio signals. The audio signals can be 15 analyzed with speech recognition circuitry to recognize certain words that correspond to system messages which are then employed to affect the operation of the device. In certain embodiments of the device, the patient's spoken commands can be used to alter the operating mode of a pacemaker, change operating parameters, or initiate recording of physiological data for later 20 retrieval. Such recorded data can include, for example, electrograms, recordings of the patient's voice, heart sounds, respiratory patterns, or indications of physical activity.

 In another embodiment, the invention is an implantable medical device, such as a cardiac pacemaker or implantable cardioverter/defibrillator, having 25 incorporated therein a system enabling voice recording by the device, with the voice recording activated by either an external or internal signal. In the case of externally activated voice recording, the external signal may be, e.g., a voice, tactile, or magnetic signal imparted to the device by the patient or physician. An internal signal may be generated by the device upon sensing a particular 30 physiological condition via its sensing channels, where the particular condition would typically be defined as one where it would be useful to have the subjective impressions of the patient while the condition is present, such as during an arrhythmic episode.

Brief Description of the Drawings

Fig. 1 is a system diagram of an implantable medical device incorporating the invention.

Description of the Invention

5 This application hereby incorporates by reference U.S. Patent Application No. 09/306,605, filed on May 6, 1999, in its entirety.

In the description that follows, a microprocessor-based pacemaker will be referred to as incorporating the present invention. It should be appreciated, however, the invention could also be incorporated into a pacemaker controlled 10 by custom logic circuitry either in addition to or instead of a programmed microprocessor. The term "circuitry" as used herein should therefore be taken to mean either custom circuitry or a microprocessor executing programmed instructions contained in a processor-readable storage medium along with associated circuit elements.

15 Fig. 1 shows a system diagram of an implantable medical device, in this case is a microprocessor-based pacemaker with defibrillation and/or antitachycardia pacing capability, that incorporates the present invention. A microprocessor 10 communicates with a system memory 12 via a bidirectional system bus. Memory 12 may typically comprise a ROM for program storage 20 and a RAM for data storage. The overall operation of the device is controlled by a system program running from the memory 12. The microprocessor also has a port for communicating with the telemetry interface 40 which in turn receives programming data from and transmits telemetry data to an external programmer 70 by a radio link. The pacemaker has atrial sensing and pacing channels 25 comprising electrode 34, lead 33, sensing amplifier 31, pulse generator 32, and an atrial channel interface 30 which communicates bidirectionally with a port of microprocessor 10. The ventricular sensing and pacing channels similarly comprise electrode 24, lead 23, sensing amplifier 21, pulse generator 22, and a ventricular channel interface 20. For each channel, the same lead and electrode 30 are used for both sensing and pacing. The channel interface includes sampling circuitry and an analog-to-digital converter for digitizing sensing signal outputs from the sensing amplifiers and registers which can be written to by the microprocessor in order to control pacing. A shock pulse generator 80 can also

be interfaced to the microprocessor for delivering cardioversion or defibrillation pulses to the heart via a separate pair of electrodes 81a and 81b. Power for the device is provided by a battery.

An acoustic transducer 50 communicates with the microprocessor via a transducer interface 51. The transducer 50 may be an accelerometer or other piezo-resistive device capable of transducing acoustical energy from the patient's body into electrical signals. When the implantable medical device is implanted into a patient, the transducer 50 is capable of producing audio signals corresponding to the patient's voice, as acoustical energy produced by the patient's larynx is radiated into the thorax as well as into the air. The transducer interface 51 includes sampling circuitry for sampling the acoustic transducer output, an analog-to-digital converter for digitizing the samples, and circuitry for interfacing to a digital signal processor 53. Filtering of the transducer signals may also be performed by analog filters in the transducer interface 51 prior to digitization to reduce aliasing effects.

The digital signal processor interfaces to the microprocessor via the system bus and may incorporate speech recognition circuitry for extracting speech information from the digitized transducer signals. Such speech information may constitute specific groups of words that can be decoded into messages recognized by the system program. When such words are spoken by the patient, the messages cause the system program to alter the operation of the pacemaker. In different embodiments, a message derived from the speech information may cause the system program to alter the operation of the pacemaker by, for example, changing its operating mode, changing the operating parameters such as minimum heart rate, or causing the pacemaker to begin storage of sampled data in a storage medium such as the system memory 12.

Examples of such data storage include samples of the acoustic transducer output which therefore constitute recordings of the patient's voice or heart sounds, and samples of the sensing channel outputs thus forming a cardiac electrogram. Time stamps may also be applied to the recordings as they are made. Other types of data as recorded by other physiologic sensors incorporated into the device could also be recorded. The recordings can be later retrieved by transmission via the telemetry interface to an external programming device.

Such recordings of physiological or voice data can then be correlated with symptoms experienced by the patient. This may be very useful to a treating physician in getting an accurate history of a cardiac event experienced by the patient, especially for those patients who are not able to adequately describe a 5 cardiac event at much later clinical visit.

In another embodiment, voice recording is initiated upon receipt by the device of either an externally derived signal or an internal signal generated by the device itself. Examples of such external signals that could be used by particular embodiments are voice commands sensed and interpreted by the 10 device as described above, operation of a magnetically-actuated reed switch with a magnet placed in proximity to the device (as is done to initiate a programming mode in conventional pacemakers), or manual operation of tactiley actuated switch by a user. In the case of a tactiley actuated switch, the tactile sensor actuating the switch could be, for example, a button placed on the outside of the 15 implanted device which a user could access by pressing on the overlying skin, or a vibration sensor or accelerometer such as acoustic transducer 50 where acoustic signals generated by tactile stimuli applied to the device (e.g., by manually tapping) are interpreted as commands to activate voice recording. In another embodiment, voice recording could be activated when an internal signal 20 is generated by the device when a condition corresponding to the onset of a physiologic or cardiac event is sensed by the device. In other embodiments, such externally and internally generated signals can be used to trigger other types of diagnostic storage including, e.g., recording of time stamps, cardiac electrograms, activity sensor outputs, and heart sound sensors, as well as to 25 affect the operation of the device such as adjusting the pacing rate within predefined limits or turning on or off sensor dependent rate-responsive features.

In order to derive speech information from the acoustic transducer output corresponding to the patient's voice or to produce intelligible voice recordings for later playback, the acoustic transducer output must be sampled at some 30 minimum rate. As both processor overhead and the memory requirements of the system increase with the sample rate, it is desirable to sample near this minimum rate. Although human hearing is capable of detecting audio frequencies up to 20 KHz, only a fraction of that bandwidth is needed to transmit

normal speech. Phone lines in the U.S., for example, restrict the bandwidth of transmitted audio signals to below 4 KHz in order to prevent aliasing distortion when the signals are digitized. A level 0 digital signal used for transmitting a single voice channel over phone lines in the U.S., for example, is a pulse code modulated signal consisting of an analog voice signal sampled with 8 bits of quantization at a rate of 8000 samples per second. It has been found that intelligible speech can still result if an audio signal is bandlimited to at least as low as 2 KHz, which implies a minimum sampling rate of 4000 samples per second. At 4000 samples per second, a memory requirement of 80 Kilobytes would be needed for a 20 second recording. This figure can be reduced still further using various data compression techniques.

The implantable medical device as described thus enables a patient to affect the operation of the device with voice commands. In order to prevent inadvertent commands being issued to the device and restrict access to its voice control feature, the system could be programmed to ignore all messages derived from transduced speech unless a specific password is first spoken. Another password could be used to cause further speech to be ignored. Alternatively, the voice control feature could be rendered inactive until a specific input signal is received which could be, for example, operation of a reed switch by a magnetic field similar to the way external programmers typically communicate with pacemakers, or operation of a tactile sensor incorporated into the device.

Although the invention has been described in conjunction with the foregoing specific embodiment, many alternatives, variations, and modifications will be apparent to those of ordinary skill in the art. Such alternatives, variations, and modifications are intended to fall within the scope of the following appended claims.

What is claimed is:

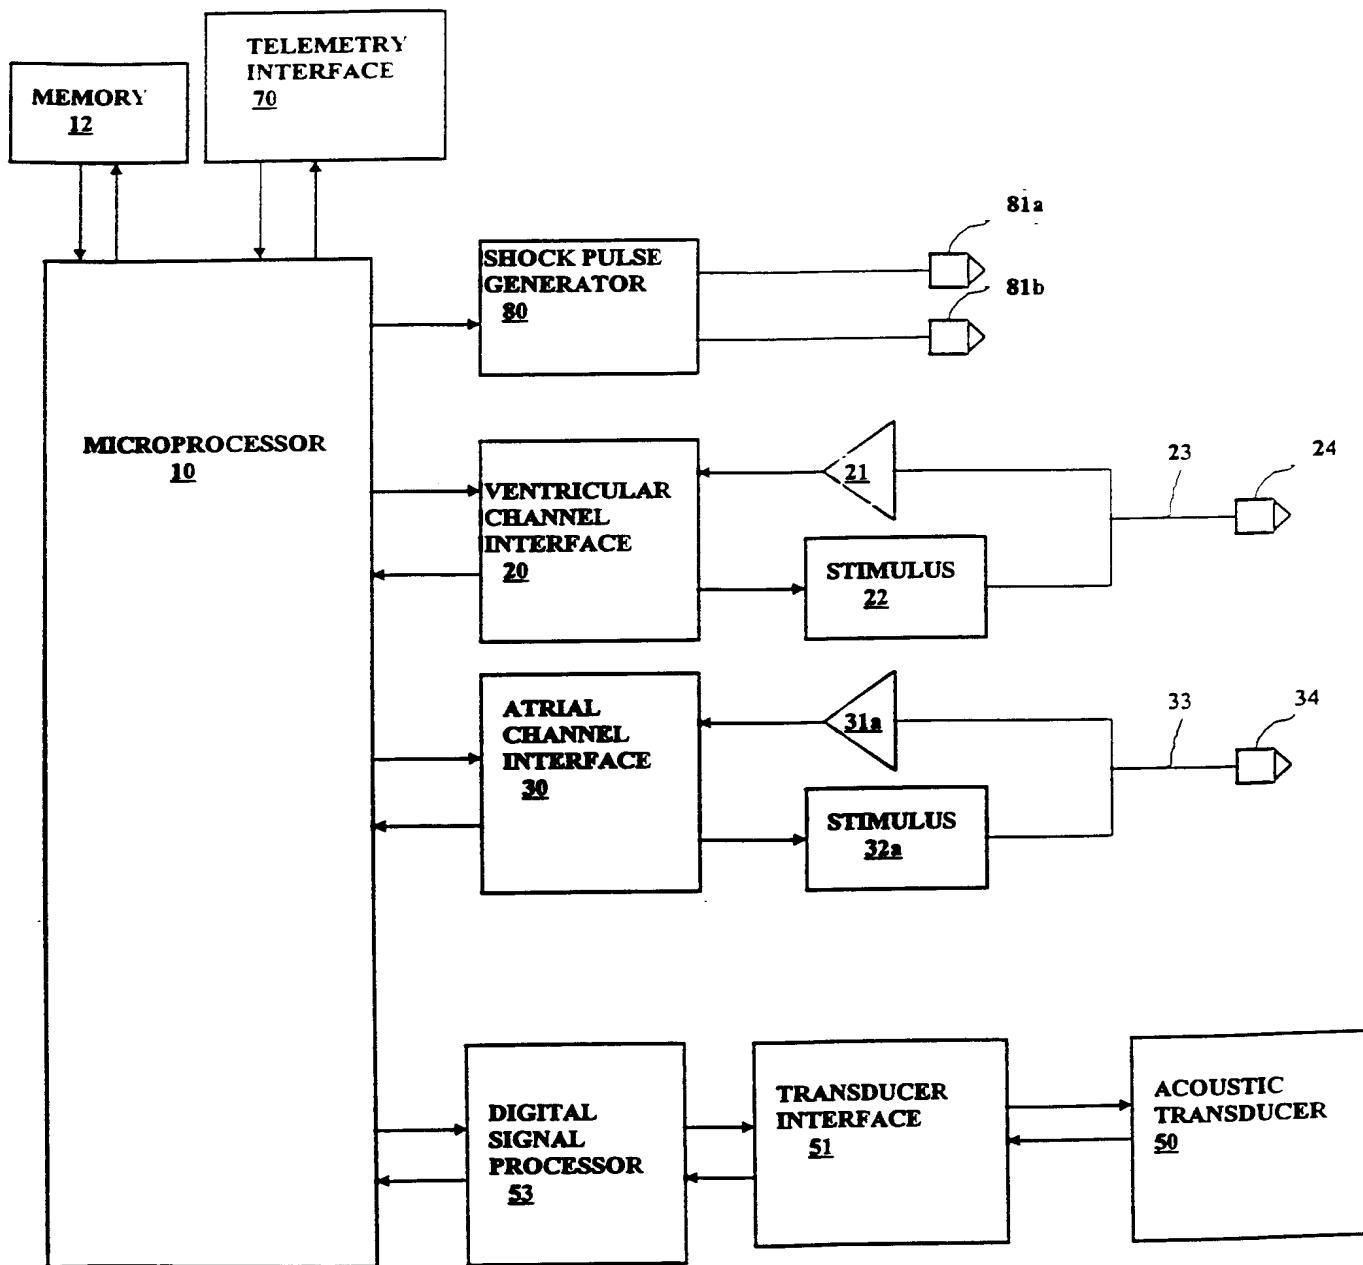

1. A medical device adapted for implantation into a patient, comprising:
 - an acoustic transducer for receiving acoustic energy from within the patient's body and generating electrical audio signals in accordance therewith;
 - 5 sampling circuitry and an analog-to-digital converter for producing digitized samples of a signal received from the acoustic transducer;
 - speech processing circuitry for analyzing the digitized signal and deriving a message therefrom; and
- 10 circuitry for interpreting the received message and altering the operation of the device in accordance therewith.
2. The device of claim 1 wherein the message interpreting circuitry ignores all messages until a message corresponding to a spoken password is received.
- 15 3. The device of claim 1 further comprising:
 - a sensing channel for sensing electrical activity of a patient's heart in whom the device is implanted;
 - circuity for producing digitized samples of the sensed electrical activity;
- 20 and
 - circuity for recording of a plurality of the digitized samples of the sensed electrical activity in a storage medium when a selected message is received.
4. The device of claim 1 further comprising circuitry for recording a time stamp when a selected message is received.
- 25 5. The device of claim 1 further comprising circuitry for enabling the coded message to cause recording of a plurality of samples of the digitized acoustic signals in a storage medium.
- 30 6. The device of claim 5 further comprising telemetry circuitry for transmitting the plurality of samples recorded in the storage medium to an external programming device.

7. The device of claim 1 wherein the implantable medical device is a cardiac device selected from a group consisting of a cardiac pacemaker, an implantable cardioverter/defibrillator, and a combination pacemaker/defibrillator and further comprising circuitry for enabling messages derived from the digitized audio signals to alter operating parameters of the device.
- 5
8. The device of claim 1 further comprising circuitry for deactivating processing of audio signals until an activation signal is received.
- 10 9. The device of claim 8 wherein the activation signal is operation of a reed switch by a magnetic field.
- 15 10. The device of claim 8 wherein the activation signal is operation of a tactile switch incorporated into the device.
11. A medical device adapted for implantation into a patient, comprising:
an acoustic transducer for receiving acoustic energy from within the patient's body and generating electrical audio signals in accordance therewith;
sampling circuitry and an analog-to-digital converter for producing digitized samples of a signal received from the acoustic transducer; and
circuitry for recording of a plurality of samples of the digitized acoustic signals in a storage medium.
- 20
12. The device of claim 8 wherein the recording circuitry is activated to initiate voice recording by operation of a magnetically actuated reed switch.
- 25
13. The device of claim 8 wherein the recording circuitry is activated to initiate voice recording by operation of a tactile switch incorporated into the device.
- 30 14. A method for controlling the operation of an implantable medical device comprising:
receiving acoustic energy within a patient's body and generating

electrical audio signals in accordance therewith;
analyzing the audio signals and deriving a message therefrom; and
interpreting the message and altering the operation of the device in
accordance therewith.

5

15. The method of claim 14 further comprising sampling and digitizing the audio signal prior to analyzing the samples to derive a message therefrom.
16. The method of claim 15 further comprising initiating storage of a plurality of digitized audio signal samples upon receipt of a selected message.
17. The method of claim 14 comprising:
 - sensing electrical activity of a patient's heart in whom the device is implanted;
 - 15 producing digitized samples of the sensed electrical activity; and
 - recording a plurality of the digitized samples of the sensed electrical activity in a storage medium when a selected message is received.
18. The method of claim 14 further comprising ignoring all messages received until a message corresponding to a spoken password is received.
19. The method of claim 14 further comprising deactivating processing of audio signals until an activation signal is received.
- 25 20. The method of claim 19 wherein the activation signal is operation of a reed switch by a magnetic field.
21. The method of claim 20 wherein the activation signal is operation of a tactile switch incorporated into the device.
